Statistics: Mean 33.516; Variance 173.687; scale 0.193

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         to the target cells for use in inhibiting HBV replication. Alternatively, a nucleic acid construct that directs overexpression of an inhibitory protein in target cells is used for the gene therapy of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Hepatitis B virus precore p25 p

PT Vaccine comprises recombinant, attenuated pox-virus - use for vaccinating against viral infections such as rables, hepatitis B, PT Waccine comprises recombinant, attenuated pox-virus - use for vaccinating against viral infections such as rables, hepatitis B, PT HIV, HSV, EBV, CMV, mumps etc.

PS Disclosure; Fig 13; 456pp; English.

The sequence given is encoded by an expression cassette which comprises a portion of the hepatitis B virus (HBV) pre-S region (S12/CCC) which is precisely linked to the I3L promoter derived from vaccinia virus. This DNA sequence was linked to the S1 and S2 core) which is precisely linked to the I3L promoter derived from vaccinia virus. This DNA sequence was linked to the S1 and S2 recombinant expressing the HBV gene. Other HBV genes were also used in the construction. These were HBV M protein (small pre-S antigen, spsAg). Each of these gene sequences were inserted individually into three different sites of NYVAC separated by from each other by large regions of vaccinia DNA containing essential genes. NYVAC is a Copenhagen vaccine strain of vaccinia virus which has been modified by deletion of six non-essential regions of the genome encoding known or potential virulence factors.

                                                                                                                 The deletion loci were engineered as recipient loci for the insertion of foreign genes. The spacing of the three inserted sequences ensured that any recombination that did occur would lead to disruption of the vaccinia genome and would cause unviable vaccinia virus. See also

This sequence contains the T cell stimulating epitopes, amino acid residue 1-55 and 70-140. It is believed that the regions 1-44 and 70-140 do not contain determinants that suppress T cell activation. Polypeptides essentially consisting of 15 to 55 amino acids corresponding to the above mentioned HBV regions are T cell stimulating. Coupling a polypeptide immunogen to such sequences, e.g. by using a bifunctional reagent which forms a disulphide link, improves its immunogenicity. These are useful in vaccines and can be therapeutically to improve T cell response to HBCAg in infected
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         wPI; 88 163287/24.

New conjugates and fusion proteins of immunogenic polypepytide and hepatitis B core antigen and T cell stimulating polypeptide coresp. to core_antigen, useful in vaccines.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  This polypeptide comprises the hepatitis B virus (HBV) 22 kDa (p22) protein that is produced by elimination of the 19-amino acid leader peptide from the 25 kDa full-length HBV precore protein (see w50250). Evidence is provided that HBV replication is inhibited in the presence of high levels of HBV precore or precore-related proteins. These proteins can be incorporated into HBV nucleocapsids of component, and thereby render the nucleocapsids deficient in encapsidating HBV pregenomic RNA. Thus, over-expression of the precore proteins, or certain variants of them, can be incorporated into HBV nucleocapsids of the inhibitory proteins, or certain variants of them, can be precore proteins, or certain variants of them, can be produced p25 (see W50250), p22, Met-p22 (see W50242), p18 (see W50236), Met-p18 (see W50237) and Met-p18 (see W50237), p18 (see W50236), Met-p18 (see W50237) and Met-p18 (see W50238), May be inserted into the p22 and Met-p22 polypeptides. The inhibitory proteins can be produced by recombinant methods using claimed expression vectors and host cells. They can be provided exogenously to the target cells for use in inhibiting HBV replication.

Alternatively, a nucleic acid construct that directs overexpression of an inhibitory protein in target cells is used for the gene therapy of HBV infection.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Matches

CC This is the 21 kDa (p21) protein of hepatitis B virus (HBV) that CC assembled into a 180 kSa subunit nucleocapsid structure that CC promotes viral replication. Evidence is provided that HBV CC precore or precore-related proteins. These proteins can be concerned into HBV nucleocapsids along with the p21 core protein can determine the nucleocapsids deficient in encapsidating HBV CC and thereby render the nucleocapsids deficient in encapsidating HBV cc pregenomic RNA. Thus, over-expression of the precore proteins or CC ertain variants of them, leads to transdominant inhibition of HBV CC preplication. Suitable inhibitory proteins include p25 (see W50250), p22 (see W50241), Met-p22 (see W50234). These proteins CC can be produced by recombinant methods using claimed expression CC vectors and host cells, and can be provided expensity to target CC ells for use in inhibiting HBV replication. Alternatively, a concleic acid construct that directs overexpression of an inhibitory conference in faction.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Matches

The inhibitory effect is species-specific and is achieved by deletion of a few C-terminal amino acids from the core protein, and/or by joining the core protein to a hepadnavirus surface protein (see also W09045), creating a core-surface fusion. Such mutant polypeptides (see also W09046-50) can be used to treat hepadnavirus, e.g. HBV,

                                                           Recombinant DNA coding for polypeptide - have specificity of hepatitis B viral antigens in detection or antibody stimulation Example: Figs 3-4; 43pp; English. Human serum from a single HBsAg positive, HBeAg positive donor (serotype adym) was used to prep. a DNA-conty, pellet which was labelled with 3H or 32P as described by P. M. Kaplan et al (1973). The labelled DNA was then extracted with phenol from the resulting pellet using the procedure of L. I. Lutwick and W. S. Robinson (1977). It was then cloned in plasmid pBR322 which was used to transform E. coli. Micro-organisms prepd. by the processes are deposited at the NCIB as pBR322-HBV-G-L, e.g. E. coli HBIO1/pBR322-Pst I dG: Tetr AmpS HBV+.

Disclosure: 4pp: English.

Polypeptide fragments encoded by the DNA sequence are antigenic for the BNA and may be used as a vaccine or in detection. Peptides may be cultured in a suitable bacterial host such as E.coli.

Fragments of the sequence are also claimed as being antigenically useful.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              (BIOJ) Biogen Inc.

                                                                                                                                                                                                                                                                                                                                            Plasmid phby DN Ac carries an insert (T49598) coding for a prot (W09048) comprising a hepatitis B virus (HBV) core protein (set also W09044) fused in-frame at amino acid 179 with the HBV suri protein (see also W09045) at amino acid 8. Plasmid phby DN BB (T49599) expresses the HBV core fused at amino acid 175 to the surface protein at amino acid 112 (W09049). PHBV DN AA was at least as potent an inhibitor of HBV replication as construct PHBV DN (T49597); PHBV DN BB was less inhibitory than PHBV DN. Vectors expressing hepadnavirus dominant negative core mutants be utilised in the gene therapy of viral infections.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             11-APR-1997 (first entry)

Human serum from a single HBsAg positive, HBeAg positive donor (serotype adym) was used to prep. a DNA-contry pellet which was labelled with 3H or 32P as described by P. M. Kaplan et al (1973). The labelled DNA was then extracted with phenol from the resulting pellet using the procedure of L. I. Lutwick and W. S. Robinson (1977). It was then cloned in plasmid pBR322 which was used to transform E. coli. Micro-organisms prepd. by the processes are deposited at the NCIB as pBR322-HBV-G-L, e.g. E. coli HB101/pBR322-Pst I dG:

Recombinant plasmid for high immunogenity virus - contains recombined haemagglutinin gene, hepatitis B core gene of vaccinia virus and exotic genes
Disclosure; Fig 9; 12pp; Japanese.

The hepatitis B core gene is recombined with PV-1 DNA and IL-1 beta to form a plasmid (047738) which is then used to propose the process.

NB: Sequence is difficult to read in the original

Disclosure; Fig 3; 13pp; Japanese.

The sequence is that of hepatitis virus core antigen (HBcAg). It can be used as a vaccine for the prevention of infections by hepatitis B virus (HBV) and also in the diagnosis of early stages of HBV infection. See also P40310.
Recombinant plasmid for high recombined haemagglutinin ger virus and exotic genes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   T 15

Database:

Statistics:

pir60 1:pir1 2:pir2 3:pir3 4:pir4

Mean 47.447; Variance 117.780; scale 0.403

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.

MPsrch_pp protein - protein database search, using Smith-Waterman algorithm

Tabular output not generated. Run on: Thu Dec 16 13:37:17 1999; MasPar time 10.33 Seconds 829.075 Million cell updates/sec

Title:

Description: Perfect Score: >US3890-1-38183 (1-303) from us3890-1-38183.pep 2263 1 MDIDPYKEFGATVELLSFLP......RRRRSQSPRRRRSQSRESQC 303

Scoring table:

PAM 150 Gap 11

Searched: 77977 seqs, 28268293 residues

Post-processing: Minimum Match 0% Listing first 45 summaries

Database: swiss-prot37 1:swissprot

Statistics: Mean 48.698; Variance 104.355; scale 0.467

Pred. No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
